# 'Study of Vision Screening in School Children between 5 and 15 Years" 

${ }^{1}$ Dr. Venugopal Reddy. I,<br>Medical Director and Consultant Paediatrician, Ovum Hospital, Bangalore.

${ }^{2}$ Dr. Rajesh Babu .M, Consultant Pediatrician, Manipal Hospital, Bangalore.

${ }^{3}$ Dr. Bhaskar Shenoy, HOD of Pediatrics, Manipal Hospital, Bangalore.

#### Abstract

:- > Background: In India, children make up $31 \%$ of the populace. There are 1.4 million blind children in the globe, according to estimates. Another 7 million people have low vision, and 10 million toddlers have a correctable refractive error that impairs their vision. The prevalence of blindness in India, despite the fact that no populationbased national study has been conducted, is thought to be $0.8 / 1000$ children in the age range of 0 to 15 years. It's crucial to identify and address preventable eye diseases and visual impairment in children as early as possible.

## > Materials

Using the standard opthal examination procedure, visual screening was conducted. Snellen's charts, common near vision charts, torch lights, direct ophthalmoscopy, retinoscopy, and auto refractor were used to test children.

## > Results:

Of the 2016 school-aged children who were evaluated, 1040 ( $51.6 \%$ ) of them were men and 976 ( $48.4 \%$ ) were women. Prevalence of ocular morbidity was 283 ( $14.04 \%$ ), refractive errors were 222 ( $11.01 \%$ ), strabismus was 6 ( $0.30 \%$ ), amblyopia was 4 ( $0.20 \%$ ), vitamin $A$ deficiency was 5 ( $0.25 \%$ ), allergic conjunctivitis was 19 ( $0.94 \%$ ), and other eye morbidities like blepheritis, hordeolum, coloboma, etc. were 27 ( $\mathbf{1 . 3 4 \%}$ ). Out of 222 kids with refractive errors, 154 (or $7.6 \%$ ) had myopia, 38 (or $1.88 \%$ ) had hypermetropia, and 30 (or $1.48 \%$ ) had astigmatism, indicating high incidence of myopia ( $P$ value 0.05 ) compared to other issues.

## $>$ Conclusion:

It was found that school-aged adolescents had a high prevalence of ocular morbidities and more refractive errors. It backs up the suggestion that vision testing of schoolchildren in developing nations could be a helpful instrument in identifying treatable causes of decreased vision, particularly refractive errors, and in minimising long-term permanent visual impairment.

School children form an important large target group for screening ocular morbidities.

## I. INTRODUCTION

There are 270,000 blind children in India, where the prevalence of blindness is reported to be $0.8 / 1000$ children in the $0-15$ age group. While refractive errors are a significant factor in both vision impairment and blindness, corneal and lenticular conditions are the most common causes of blindness. Common vision impairments, such as myopia, are typically acquired and progressive. Refractive errors are more common in some states and countries than others, and this varies according to socioeconomic standing, environmental factors, genetic make-up, race, ethnicity, and climate, as well as access to medical treatment (1). One of the leading causes of blindness is refractive error, and the years of blindness brought on by these diseases place a significant economic and social burden on both communities and people. Childhood blindness is considered as one of the five causes of avoidable blindness under the Global initiative for eliminating avoidable blindness. (2)

There is no question about the significance of early detection and treatment of preventable eye diseases and vision impairment in infants. In order to prevent childhood blindness, it is essential to pinpoint significant preventable causes in each nation and track the evolving trends of children who are severely visually impaired or blind over time in various parts of the nation (3). Measles, stress, traditional harmful practises (TMP), autosomal dominant diseases, and TORCH infection are examples of preventable causes. Cataract, glaucoma, amblyopia, refractive errors, retinopathy of prematurity, and congenital cataract are all treatable reasons. High measles vaccination rates, breastfeeding support, health and nutrition instruction, and ongoing initiatives to combat Vitamin 'A' deficiency through child survival programmes are all part of primary prevention. $(4,5)$

## II. MATERIALS AND METHODS

$>$ By carefully and methodically examining the eyes of schoolchildren between the ages of 5 and 15 (from first grade to tenth grade), the current research aims to determine the prevalence of common eye problems among children attending schools in Bangalore.
$>$ A detailed action plan was created and distributed to all schools where screening was meant to take place.
$>$ A distinct document sent to each school's headmaster during the student screening process.
$>$ The goal and procedure of the student examination were explained to the class teachers and the physical education teachers during the teachers' orientation.

- The Team.
$\checkmark$ Paediatrician
$\checkmark$ One Ophthalmologist / P.G. in Ophthalmology.
$\checkmark$ One Senior Ophthalmic assistant.
$\checkmark$ Two junior staff / Paramedical Ophthalmic Assistant students.

The school personnel assisted and actively participated in the screening, which was carried out on pre-arranged fixed dates in accordance with the schedule. The indicated date was used to tour each school during regular business hours. Teachers were requested to gather introductory information such as name, age, class, etc.

An expansive room ( 6 metres long) with an electrical source and plugging infrastructure was chosen for screening. Each student underwent visual acuity tests with the assistance of the physical education instructor and the class teacher.

Students who had vision of $6 / 9$ or less underwent a thorough evaluation, which included retinoscopy and fundus examination.

## > Method of Examination:

- The Snellen visual acuity letters chart was used to measure visual acuity at both a distance of 6 metres and a close distance of 33 centimetres. When required, a ' $E$ ' letter card with four identical optotypes was also used. Both children who wore glasses and those who did not were examined. A 33 cm distance was used for the close vision test using the common near vision charts.
- A thorough inspection of the eyes using a torch and loupe in diffuse lighting to look for any adnexal and anterior segment diseases. Children with normal vision
(6/6), no complaints, or other obvious results were not subjected to refraction and thorough testing.
- Children with eye acuity of $6 / 9$ or less underwent a thorough examination.
- The cover test and the cover-uncover test for extraocular motility and muscular balance.
- The digital tension in each eye was assessed, and the results were contrasted. Where suitable, the confrontation technique was used to evaluate visual fields.
- Direct ophthalmoscopy to validate the clarity of the visual axis, rule out media opacities, and fundus pathology.
- Verbal informed consent from parents or instructors for any necessary cycloplegic procedure.
- Examining the refractive state of the eye: To increase the validity of the screening program, children with visual acuities of $6 / 9$ or less were grouped individually and reassessed after finding the visual acuities of each eye with and without glasses. They were closely inspected. Cycloplegic refraction was used on kids with pin-hole enhancement. For those kids who didn't better their pinholes, a more thorough examination was performed to check if any ocular pathologies were present. Children who had pinhole improvement but could not read any of the lines on Snellen's chart were classified separately as doubtful amblyopics. These two groups of kids were assigned for additional assessment and management.
- Retinoscopy and auto refraction were performed on toddlers whose visual acuity was $6 / 9$ or less.
- In order to determine the prevalence of refractive errors in school-aged children, myopia, hypermetropia, and astigmatism in either or both eyes equivalent to or more than absolute value of 0.5 D were taken into account for the analysis of data.
- Refractive mistake correction is one of the services offered.(b) The management of common allergies and eye infections at the classroom level.(c) Children were given $2 \mathrm{ml}(2,00,000$ I.U.) of vitamin A syrup on two successive days in accordance with the schedule, and were then monitored for up to six months.services for referring those who need additional testing or therapy. (Neuro-ophthalmology, paediatrics etc.).
- Children, school staff, and parents receive health education about the importance of ocular hygiene and eye health care, teacher orientation programs, classroom illumination, maintaining good posture while reading and writing, the importance of good nutrition, and the signs, symptoms, and complications of refractive errors and other ocular conditions. They also received advice on how to properly wear eyewear and schedule followup appointments. (once in 6 months to 1 year).

## III. OBSERVATION AND RESULTS

Table 1 Distribution of Children Screened

| No. of students screened | Males | Females |
| :---: | :---: | :---: |
| 2016 | 1040 | 976 |
| $\%$ | 51.6 | 48.4 |

Fig 1 Sex Distribution
Out of 2016 students screened for ocular morbidities $1040(51.6 \%)$ are males and $976(48.4 \%)$ are females.
Table 2 Distribution of different Refractive Errors and other Ocular Morbidities ( $\mathrm{N}=2016$ )

| SL | Ocular Morbities | No | $\%$ | P-value |
| :---: | :---: | :---: | :---: | :---: |
| $\mathbf{1}$ | Myopia | 154 | 7.64 | $0.032^{*}$ |
| $\mathbf{2}$ | Hypermetropia | 38 | 1.88 | 0.56 |
| $\mathbf{3}$ | Astigmatism | 30 | 1.49 | 0.324 |
| $\mathbf{4}$ | Vitamin-A Deficiency | 5 | 0.25 | 0.86 |
| $\mathbf{5}$ | Strabismus | 6 | 0.30 | 0.441 |
| $\mathbf{6}$ | Amblyopia | 4 | 0.20 | 0.689 |
| $\mathbf{7}$ | Allergic Conditions | 19 | 0.94 | 0.714 |
| $\mathbf{8}$ | Others | 27 | 1.34 | 0.362 |
|  | Total $\boldsymbol{1 4 . 0 4 \%}$ | $\mathbf{2 8 3}$ |  |  |

Fig 2 Distribution of different Refractive Errors and other Ocular Morbidities (N=2016)

Of the total number of children 2016 screened, 283 (14.04\%) have ocular morbidities, most prevalent is myopia 154(7.64\%) with P -value of $<0.05$.

Table 3 Prevalence of Refractive Errors and Confidence Interval Determination

| SL | Total No. of Students Examined | No. of Students with Refractive Errors | Prevalence | CI-95\% |
| :---: | :---: | :---: | :---: | :---: |
| 01 | 2016 | 222 | $11.01 \%$ | $9.28-12.36$ |

Fig 3 Prevalence of Refractive Errors and Confidence Interval Determination
The above table shows Prevalence of Refractive Errors in school children as $11.01 \%$. The present study is compared with the study conducted by Kalikivayi.V et. al.and by Rakhi Dandona et. al., study conducted in Andhra Pradesh, South India (Rural), study by Mausumi Basu, Palash Das et.al,. in surat (urban) in North India and study by Munoz B, West SK on Americans and Caribbeans.

Table 4 Distribution of different types of Refractive Errors among Chidren

| Type of RE | No. of Students with RE | Percentage | P-value |
| :---: | :---: | :---: | :---: |
| Myopia | 154 | 7.639 | 0.021 |
| Hypermetropia | 38 | 1.885 | 0.362 |
| Astigmatism | 30 | 1.488 | 0.652 |
| Total | 222 | 11.01 |  |

Fig 4 Distribution of different types of Refractive Errors among Chidren

This table shows out of 222 ( $11.01 \%$ ) children with refractive errors, children with Myopia are 154(7.6\%),Hypermetropia are $38(1.89 \%)$ and astigmatism are $30(1.49 \%)$.Indicates that prevalence of myopia is more compared to other refractive errors with significant finding of P value $<0.05$.

Fig 7 Pattern of Myopia According to distribution of Age
A $69.36 \%$ specific incidence of myopia was discovered. Therefore, compared to hypermetropia, myopia was found to be the most significant and prevalent pattern of refractive error in the current research, and it was more common in older age groups. Myopia prevalence rose from $62.16 \%$ in the 5 to 9 year age group to $72.97 \%$ in the $10-15$ year age group, suggesting that myopia prevalence increased with age.

| Chi square | $6.44^{*}, \mathrm{P}<0.05$ |  |  |  |  |  |

Fig 10 Myopia according to Age and Sex

Myopia was found to be more common in males of younger age group, whereas it was equally distributed among males and females of older age group.

Table 12 Prevalence of Hypermetropia according to distribution of Age

| Age Group (years) | Total no of Students with RE | $\boldsymbol{\%}$ | Students with Hypermetropia | Percentage |
| :---: | :---: | :---: | :---: | :---: |
| $\mathbf{5 - 9}$ | 74 | 3.67 | 18 | 0.89 |
| $\mathbf{1 0 - 1 5}$ | 148 | 7.34 | 20 | 0.99 |
| Total | 222 | 11.01 | 38 | 1.88 |
| Chi square | $3.98^{*} \mathrm{p}<0.05$ |  |  |  |

Fig 11 Prevalence of Hypermetropia according to distribution of Age
It was discovered that pupils with RE had a specific prevalence of hypermetropia of $1.88 \%$ of $11.01 \%$, or $17.7 \%$. Children under the age of 10 had a higher prevalence of hypermetropia than those over that age. As people get older, hypermetropia is less common with a P-value of 0.05 , this result is extremely significant.

Table 13 Age wise distribution of Hypermetropia

| Age in years | Males | \% | Females | \% | Total | \% |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{5}$ | 2 | 0.19 | 0 | 0 | 2 | 0.09 |
| $\mathbf{6}$ | 2 | 0.19 | 0 | 0 | 2 | 0.09 |

| Total | $\mathbf{2 2 2}$ | $\mathbf{1 6}$ | $\mathbf{7 . 2 0}$ | $\mathbf{1 4}$ | $\mathbf{6 . 3 0}$ | $\mathbf{3 0}$ | $\mathbf{1 3 . 5 1}$ |

Fig 13 Pattern of Astigmatism according to Age and Sex distribution
Prevalance of astigmatism was similar and equal among younger and older age group of students. The specific prevalence of astigmatism was found to be $13.51 \%$. It was found that Astigmatism was the least common type of refractive error while Myopia was the most common type.

Table 15 Mean Age of Students with Hypermetropia

| Sex | Mean in years | SD |
| :---: | :---: | :---: |
| Males | 8.4 | 2.04 |
| Females | 11.78 | 2.21 |
| Total | 10 | 2.18 |

Mean age of students with hypermetropia was found to be $10 \pm 2.18$. Mean age in male students was 8.4 years while it was 11.78 years among females.

Table 16 Mean Age of Students with Astigmatism

| Sex | Mean Age in years | S.D. |
| :---: | :---: | :---: |
| Males | 10.13 | 2.16 |
| Females | 11.43 | 2.01 |
| Total | 10.73 | 2.07 |

Mean age of students with astigmatism was found to be $10.73 \pm 2.07$ years.
Table 17 Pattern of distribution Astigmatism according to Age distribution

| Age group (years) | Total no. of students with <br> RE | Total no. of students with <br> Astigmatism | Percentage |
| :---: | :---: | :---: | :---: |
| $5-9$ | 74 | 10 | 4.50 |
| $10-15$ | 148 | 20 | 9.00 |
| Total | 222 | 30 | $\mathbf{1 3 . 5 1}$ |

Fig 14 Pattern of distribution Astigmatism according to Age distribution
Astigmatism was more prevalent among older age group both in males and females.(9.00\%)
Table 18 Pattern of Astigmatism according to Sex distribution

| Sex | No. of Students with Astigmatism | Percentage |
| :---: | :---: | :---: |
| Males | 16 | $1.53 \%$ |
| Females | 14 | $1.43 \%$ |
| Total | 30 | $1.48 \%$ |

Fig 15 Pattern of Astigmatism according to Sex distribution
Distribution of astigmatism was found to be slightly more among male children compared to that of female children.
Children of all ages and both sexes who made up the research sample as a whole had a prevalence of refractive errors that was found to be $11.01 \%$ overall. Myopia prevalence was $7.639 \%$, hypermetropia prevalence was $1.885 \%$, and astigmatism prevalence was $1.48 \%$. Myopia was more common in males than in females of the same age group in younger children, but it was similarly common in both sexes of the older age group.

Male children were slightly more likely than female children to experience all three kinds of refractive errors. In contrast to female children of older age groups, male children of younger age groups had increased chance of hypermetropia.

Table 19 Prevalence of Amblyopia

| No. of Children Examined | Males | Females | Children with Amblyopia | Prevalence |
| :---: | :---: | :---: | :---: | :---: |
| 2016 | 0 | $4-(0.198 \%)$ | $4(0.198)$ | $0.198 \%$ |

Fig 16 Prevalence of Amblyopia
The above table shows the prevalence of amblyopia. Out of 2016 children examined, 4 children had amblyopia and all 4 were female.

Table 20 Prevalence of Strabismus

| No. of Children Examined | No. of Children With Strabismus | Males | Females |
| :---: | :---: | :---: | :---: |
| 2016 | $6-(0.29 \%)$ | $4-(0.198 \%)$ | $2-(0.099 \%)$ |

Fig 17 Prevalence of Strabismus
The above table shows the prevalence of strabismus. Out of 2016 children examined, 6 children had strabismus of which 4 males and 2 female children.

Table 21 Prevalence of Allergic Conjunctivitis

Fig 19 Prevalence of Common Eye Problems

One hundred and seventy-seven of the 2016 children who were evaluated had minor ocular abnormalities other than refractive errors, vitamin A deficiency, strabismus, amblyopia, and allergic conjunctivitis. Blepheritis, meibomitis, hordeolum externum, etc. were among them. One youngster had asymmetrical pseudophakia. (operated for traumatic cataract).

All of the children listed above who had minor (treatable) eye issues like blepheritis, blephero-dermatitis, meibomitis, hordeolum, etc. were given the proper treatment advice and requested to visit Manipal Hospital Bangalore for follow-up care.

Visual acuity measurements unaided and also which improved with subjective refraction readings in both eyes are tabulated according to the pattern of refractive error and other ocular conditions causing diminution of vision in the master chart.

## IV. DISCUSSION

In the present study, a total of 2016 school children aged 5 to 15 years underwent vision screening out of which, 1040 were males ( $51.59 \%$ ) and 976 were females ( $48.41 \%$ ).

Table 23 Showing Comparison of the Present Study with Similar Studies

| Place of study / Year | Study conducted by | Age group | Sample size | Prevalence of RE in \% |

| :--- |

235 children in the study group had unaided visual acuities of $6 / 9$ or better in one or both eyes, 222 of whom had visual acuities of less than $6 / 9$ owing to refractive errors like myopia, hypermetropia, and astigmatism. Six children with strabismus, four children with amblyopia, two children with genetic anomalies (chorioretinal coloboma and iris coloboma), and one child with traumatic (unilateral) blindness all had visual acuities of less than 6/9.

The theory that myopia is promoted by reading for extended periods of time without adequate illumination and close work is consistent with the parent's instruction about myopia in children. In fact, if parents with greater education levels typically had myopia, the observed association may have a genetic basis. One explanation for the variations in refractive errors between urban and rural populations examined in various regions of our country was provided by this. There was no discernible difference in the prevalence
of refractive error in the current study between children who were male ( $11.15 \%$ ) and female ( $10.86 \%$ ). The age group of children between the ages of 11 and 12 has been found to have the highest prevalence of refractive error ( $1.59 \%$ ), with female children having a greater prevalence (1.43\%) than male children ( $1.54 \%$ ), and children under the age of 5 having the lowest prevalence ( $0.10 \%$ ). Refractive error prevalence rose from $3.57 \%$ in the age range of 5 to 9 years to $7.44 \%$ in the age range of 10 to 15 years, indicating that the incidence of refractive errors rises with age.

The prevalence of myopia rose from $2.28 \%$ in the age group of 5 to 9 years to $5.357 \%$ in the age group of $10-15$ years. Myopia was found more frequently in this age range. Out of 154 myopes, 50 kids had a family history of myopia.

Myopia prevalence is influenced by both genetic and environmental variables. The quality of education received also clearly plays a role in this frequency. From the perspective of the widely accepted theory for the development of myopia, genetic factors, dietary factors, and the amount of close work, this can be examined.

Refractive Error Study in Children (RESC) was a population-based cross-sectional study of school-aged kids between the ages of 5 and 15 to determine the prevalence of refractive error and vision impairment in people of various racial and ethnic backgrounds. The investigations were carried out in India, Nepal, China, and Chile. Out of the 2016 children tested, VAD in children was found in 5 of them. In the current research, the prevalence of vitamin-A deficiency was 0.25 percent, which was more prevalent in male children and those who were younger in age.

All five kids had Bitot's patches, but only one had corneal xerosis. All five vitamin A-deficient kids had average visual acuity, though. All of the aforementioned kids received therapeutic amounts of vitamin A (in the form of an oral suspension of retinol palmitate), and were observed for six months. Health education was provided to the affected children's classmates, instructors, and parents, as well as information on vitamin-A-rich foods.

Six of the 2016 toddlers whose eyes were examined had strabismus, including 4 boys and 2 girls. Five of the six exotropia-affected infants have decreased vision in the affected eye. After explaining to the parents and the concerned teachers the need for frequent follow-up for a long time as well as the visual prognosis, all the strabismusafflicted children in the aforementioned list were transferred to the squint clinic at Manipal Hospital for further assessment and management.

Amblyopia: Of the 2016 births, 4 of the amblyopic infants were female and aged $6,8,9$, and 13 respectively. For additional assessment and treatment, the Ophthalmic section at Manipal Hospital received referrals for all four kids.

Allergic conjunctivitis: Of the 2016 children analyzed, 19 children- 13 boys and 6 girls-presented with allergic conjunctivitis of different severity. Male children of higher ages were more likely than female children to develop vernal conjunctivitis. Atopic allergic conjunctivitis was more common in toddlers who were female. All of the aforementioned kids were given the go-ahead for the proper care and follow-up at the Manipal Hospital Ophthalmic Unit's outpatient section after two weeks, as well as any additional follow-ups that might be required. Health instruction was provided to kids, parents, and instructors on topics like ocular hygiene, personal hygiene, and avoiding allergens and pets. They were also informed about the disease's chronic character, recurrences, and the requirement for frequent, long-term follow-ups.

## V. CONCLUSION AND RECOMMENDATIONS

The main eye morbidity was discovered to be refractive errors, which accounted for $11.01 \%$ of cases. Allergic conjunctivitis came in second with $0.94 \%$ of cases, and other conditions with prevalences of less than $0.5 \%$ included unilateral amblyopia, congenital anamolies, blepharitis, stye, chalazion, and traumatic unilateral blindness.

According to the aforementioned research, school-aged children are more likely to experience refractive errors. Symptomatic refractive errors are present in the majority of these pupils.Despite the fact that many kids are already myopic when they undergo screening, very few of them receive frequent ophthalmologist checkups and wear the right corrective lenses.

Therefore, frequent screenings for ocular and visual morbidity in school-aged children are necessary. Refractive error can be easily, affordably, and effectively treated. The provision of high-quality, reasonably-priced ophthalmic care ought to be a fundamental component of the screening programme. We can also identify treatable causes of decreased vision early in life, which helps to reduce longterm, permanent visual impairment, which will have a negative impact on a child's ability to learn and develop.

For the purpose of early discovery of ocular morbidities, routine visual screening of school children, particularly those aged 5 to 15 , is highly advised.The children should be screened as part of a standard immunisation procedure. According to the findings of the aforementioned research, screening preschool children is advised in order to identify and treat ocular morbidities and conditions that cause refractive errors as early as possible.

Along with refractive error testing, a school eye health programme must provide teachers with orientation regarding prevalent eye issues. Through health talks, slide shows, and modest eye care displays, health instruction should be provided regarding ocular hygiene, classroom lighting, and nutrition.

Each kid should go through a required visual screening at least twice while attending school, spaced 4 to 5 years apart, and children who wear glasses should have an eye exam every 6 to 10 months.
